CIVIL ENGINEERING DEPARTMENT
2017
Introduction

1. Supplementary cementitious material (SCM) – Fly Ash
2. Quantitative understanding of the efficiency of fly ash as a mineral admixture in concrete is essential for its effective utilization.
3. Fraction of portland cement that can be replaced by a SCM at an unchanged strength.
4. Efficiency of Fly ash – Bolomey’s empirical equation
5. MLR and ANN
6. Cost economic analysis
Experimental Investigation and Prediction of Fly Ash Efficiency Factor in Concrete with Cost Economic Analysis

- **Phase I:** Efficiency Factor of SCMs in Concrete.
- **Phase II:** Application of Soft Computing Techniques
- **Phase III:** Concept of Efficiency factors of SCMs
- **Phase IV:** Summary

**Literature Review**

- Statement of the problem
- Research Objectives
- Expected Outcomes

**Concept Formulation**

- Laboratory Experimental Data
- RMC Plant Data

**Data Collection**

- Regression Analysis
- MATLAB learning
- Artificial Neural Network

**Soft Computing**

**Research Outcome**

- Optimum content of Fly ash.
- Prediction Model saves time.
- Possible to design concretes for a desired strength at any given age and replacement levels.
Objective of the study

1. To save the resources used in concrete like cement and aggregates.
2. To produce durable and economical concrete mix design.
3. To investigate the effects of various replacement levels of fly ash on compressive strength and workability of concrete.
4. To predict the Efficiency factor of fly ash at different levels of replacements using ANN and MLR.
5. To develop efficiency factor model which, could be helpful in the design of fly ash concretes at different age, at different level of replacement, and different water-binder ratio with greater confidence.
6. Efficiency factor model can be used as a tool for a more efficient proportioning of blended concrete.
Motivation of the study

1. These days’ fly ash are used for enhancement of concrete properties.
2. Use of fly ash is gaining importance due to its vital characteristics.
3. Fly ash and other SCMs help in developing high performance concrete (Babu and Rao, 1993).
4. This study aims at determining efficiency factor \((k)\) for fly ash.
5. The efficiency factor helps in economic mix design of supplementary cementitious materials.
Scope of the study

1. When $k=1$, CHR almost equal to PR

2. When $k>1$, it indicates the SCM used is more efficient than cement, as hydration process is fast compared to OPC. In such a case saving of cement is possible resulting economic mix design of concrete.

3. When $k<1$, it indicates the SCM used is less efficient than cement as hydration process is slow compared to OPC. In such a case more quantity of SCM should be used to achieve required target strength.

4. The efficiency of SCMs with regard to compressive strength and workability in concrete was investigated using MLR and ANN approach.

*CHR = cement hydration rate, PR = pozzolanic reaction
Efficiency Factor

1. Supplementary cementitious materials (SCMs), such as fly ash, pozzolan or blast furnace slag, are widely used to produce blended portland cements. 

2. They lead to a significant reduction in CO$_2$ emission in the production phase. 

3. A practical and generally accepted approach to evaluate the contribution of SCMs to the strength of the hardened concrete is through the concept of the SCMs efficiency factor (i.e. $k$-value concept). 

Smith (1967) determined ‘$k$’ based on the relation between concrete compressive strength and the water cement ratio ($w/c$) and obtained the efficiency of fly ash using…

$$w/c_o = w/(c+kF)$$

Where, ‘$k$’ is the efficiency factor, $c_o$ is the cement content of normal concrete, $c$ is the cement content of the equivalent binder, and $F$ is the fly ash content in a concrete of equal strength.

Materials

1. **Cement**: Ordinary Portland cement 43 grade confirming to IS:8112-1989; Specific gravity is 3.15.

2. **Fly ash**: Ashtech (India), Class F Fly Ash.

3. **Fine Aggregate**: Locally available crushed sand, confirming to Zone-II used as fine aggregate, sourced from a quarry in Turbe, Mumbai, India.

4. **Coarse Aggregate**: Locally available coarse aggregates of size 10mm and 20mm, sourced from a quarry in Turbe, Mumbai, India.

5. **Water**: Potable water confirming to IS 456-2000 is used

6. **Admixture**: Polycarboxylic ether (Sikaviscocrete5210NS).
Methodology- Bolomey’s Law

1. The Bolomey’s empirical expression frequently used to predict the strength of concrete.

2. Efficiency factors found from this strength equation are used to describe the effect of the SCMs replacement.

3. Efficiency factors are generally used to describe the impact of SCMs replacements on the compressive strength of Concrete mixes.

4. The Bolomey’s strength equation is:

\[ S = A\left(\frac{c}{w}\right) + B \]

- \(S\) is compressive strength in MPa,
- \(c\) is cement content in kg/m\(^3\),
- \(w\) is water content in kg/m\(^3\).
- \(A\) and \(B\) are constants
Multi-linear Regressions (MLR)

1. Linear regression attempts to model the relationship between two variables by fitting a linear equation to observed data.

2. One variable is considered to be an explanatory variable, and the other is considered to be a dependent variable.

3. MLR attempts to model the relationship between two or more independent variables and dependent variables by fitting a linear regression equation to observed data.

4. If it is assumed that the dependent variable \( y \) is affected by \( m \) independent variables \( x_1, x_2, \ldots, x_m \) and a linear equation is selected for the relation among them, the regression equation of \( y \) can be written as:

\[
y = a + b_1x_1 + b_2x_2 + \cdots + b_mx_m
\]
Artificial Neural Network (ANN)

2. Ability to learn from empirical data information.
3. Ability to imitate the brain's activity to make decisions and draw conclusions when presented with complex and noisy information.
4. A neural network model’s degree of success in predicting the efficiency factor largely depends on the availability of a large variety of pre-existing experimental data.
5. The experimental data, however, showed the ability of learning the network in all aspects of the relationship between the concrete mixture variables.

MLR Models for different grades of concrete

\[ k_{m40} = -85.636 \times OPC + 3.824 \times FA + 116.560 \times ADM + 8.243 \times W/C + 62.560 \]

\[ k_{m35} = 10.673 \times OPC - 0.214 \times FA - 11.656 \times ADM + 5.435 \times W/C - 9.512 \]

\[ k_{m30} = -201.244 \times OPC + 8.730 \times FA + 284.110 \times ADM + 8.795 \times W/C + 145.314 \]

\[ k_{m25} = -141.073 \times OPC + 6.901 \times FA + 205.173 \times ADM + 7.995 \times W/C + 99.259 \]

\[ k_{m20} = -85.582 \times OPC + 5.009 \times FA + 129.053 \times ADM + 7.015 \times W/C + 55.776 \]

Where \( k \) represents efficiency factor, \( m40, m35, m30, m25, m20 \) are the grade of concrete at different replacement levels of fly ash respectively, \( OPC \) is ordinary portland cement in kg/m³, \( FA \) is fly ash in kg/m³, \( ADM \) is admixture in kg/m³ and \( W/C \) is water by cement ratio.

Summary and Conclusions

**Bolomey’s empirical equations**

1. The Bolomey’s empirical expression can be used to predict the strength efficiency factors of Fly ash in concrete mixes at different percentage of replacement levels.

2. The k factor concept is suitable for Class F fly ash. It is useful for estimating the degree of the pozzolanic activity of high calcium Class fly ash and compressive strength of concrete.

3. The k values obtained from the efficiency estimate equations range from -0.51 to 1.06 at FA replacement ratios of 20-35% and water-cement ratio of 0.34-0.47.

4. The k value obtained from regression analysis can be further used as a means of mix design and quality control of FA concrete.

5. For M35 concrete mix, Efficiency of Fly ash varies between 1.03 and 1.06 for percentage replacement levels varying from 20 to 35%.
Efficiency factor at different replacement levels

1. Except M35 grade of concrete the others combinations are having negative value of efficiency factor.

2. M35 concrete is showing a constant positive value of efficiency factor. this may be due to pozzolanic reaction is faster than cement hydration rate.

3. Higher k values for M35 mix at 20% replacement of fly ash were found, indicating that fly ash can be efficiently utilized for M35 mix as compared to other mixes.
MLR and ANN

1. Based on the multi-regression analysis results, R square value comes out an average of 0.97.

2. Based on the ANN predicted results, R square value comes out an average of 0.98 which shows a good co-relation between the input parameters and dependent output variable.

3. Comparing results of ANN and MLR model, it has been observed that ANN models provide better results than MLR models.

4. The models performance, it can be seen that both ANN and MLR model results are closer to the observed results and the majority of result are being located on the line of equality (linear).
Cost Economic Analysis

1. The efficiency factor for all the mixes are positive and on an average 30\% replacement of class F fly ash with OPC is optimum.

2. For M30 and M25 mixes the replacement level of fly ash was 35\% and efficiency factor is 0.14 and 0.18 respectively.

3. The cost analysis shows and efficient use of fly ash and economical mixes in case of M30 and M25 concrete.

4. The replacement-based efficiency factor may be employed in conjunction with other factors, such as those related to cost for optimization and effective use of an additive in concrete at various replacement levels.
Future Scope

1. The above developed statistical model proved to be reasonable and feasible, showed a satisfactory performance, and demonstrated its ability to predict the efficiency of Fly ash.

2. Further work is required to develop neural network models for predicting the efficiency factor of other SCMs, such as ground granulated blast furnace slag, silica fume, rice husk ash and natural pozzolans.

3. These models will be necessary to establish the reliability of the proposed method, particularly with respect to its incorporation into the design of blended concrete.

4. Further, method of soft computing such as Genetic Algorithm can be applied for optimization of SCMs and developed a reliable model which easily modify the content of mix proportions.
